Aim: To develop a novel fabrication technique for rapid prototyping of nanodevices from InSb quantum wells

Background

Standard fabrication techniques for making nanodevices from semiconductors are **complex**, **time-consuming** and require photomasks which are **expensive**. We explore the use of **focused ion beam (FIB)** lithography for the nanomachining of devices from InSb quantum well materials. The FIB instrument uses a beam of ions to remove atoms from the sample surface. This flexible technique is a **'direct-write'** method, making fabrication quick as well as allowing for the testing of different etching chemistries and electrical properties in-situ^[1]. This makes the FIB ideal for rapid-prototyping of novel devices within the R&D context.

Results

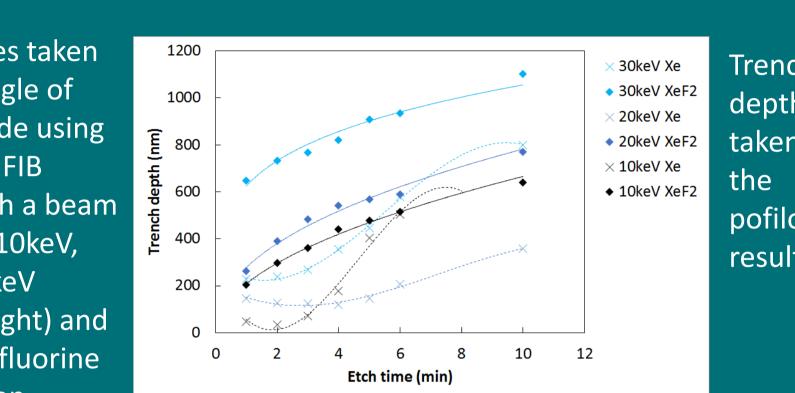

SEM images taken at a 55° angle of etches made using Xe plasma FIB milling with a beam energy of 10keV, 20keV, 30keV without (right) and with (left) fluorine gas injection.

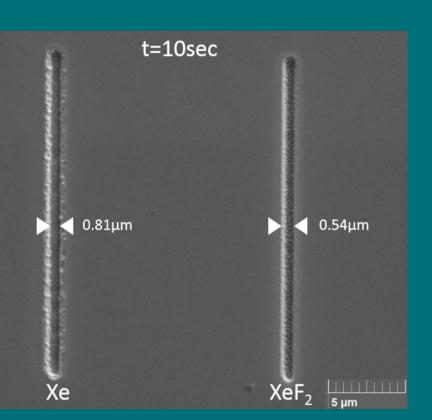

XeF₂ chemistry increases etch rate, produces

higher resolution features and less sputtered

material compared with just the Xe beam

Trench
depths
taken from
the
pofilometry
results

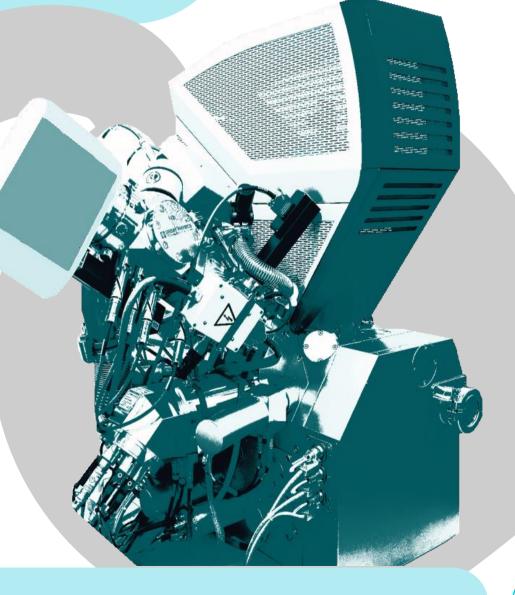

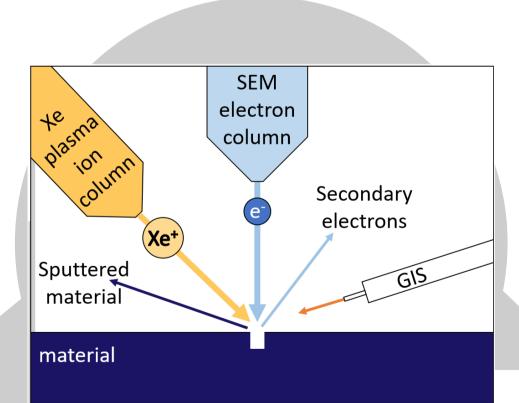

SEM image of trenches made using Xe (left) and XeF₂ (right) etching. Etching parameters were 30keV beam energy, 100pA beam current, and 10 sec etch time

Resolution of 540nm trench width achieved with XeF₂, 100pA beam energy & 10sec etch time

Methods

- The Xe plasma FIB was used to etch
 trenches into the InSb quantum wells
- Various beam parameters and the addition of a fluorine chemistry (XeF₂) was explored
- After etching, scanning electron microscope images were taken and the surface scanned using a profilometer to assess etch depth and quality

d.shearer@surrey.ac.uk

Conclusions

This study lays the groundwork for developing InSb-based nanoscale quantum devices. InSb has low effective mass, high mobility, and strong spin-orbit coupling making it an ideal material for applications such as spintronics^[2], but until now fabrication challenges^[3,4] have slowed the development of innovative InSb-based spintronics devices.

XeF₂ is a suitable ion beam etching regime for InSb/ InAlSb

The fabrication toolkit developed can produce resolution

advantages of the FIB system for R&D applications

comparable to conventional lithography techniques with the

quantum wells for making nanodevices
